We study calibration procedures of the staggered quarks on anisotropic lattices in the quenched approximation and in $N_f = 2$ dynamical simulations. For the calibration conditions we adopt the hadronic radii r_0 and the meson masses in the temporal and spatial directions. On the quenched lattice, we calibrate the quark field and compare the result with the result determined using the meson dispersion relation. In dynamical simulations, we determine the anisotropy parameters γ_G and γ_F simultaneously within 1% accuracy at renormalized anisotropy $\xi = a_s/a_t = 4$.

1. Introduction

Anisotropic lattices realize small temporal lattice spacings while keeping modest computational costs. The technique is useful in various fields of lattice QCD simulation: At finite temperature the large number of degrees of freedom in Euclidean time direction leads large number of Matsubara frequencies, which is efficient for calculation of the equation of state [1] and for analyses of temporal correlation functions [2,3,4]. The large temporal cutoff is important for relativistic formulations of heavy quarks on lattices [5]. It is also convenient for the correlators in which noises quickly grow as time such as glueballs [4,6] and negative parity baryons [7].

However, uncertainties of anisotropy parameters bring additional errors into the observed quantities. For precise calculations, we need to tune anisotropy parameters with good statistical accuracies and to control the systematic errors in the continuum extrapolations. In this work we discuss the tuning procedures of anisotropy parameters for the staggered fermions in the quenched and dynamical QCD simulations. Our goal is to tune anisotropy parameters within 1% statistical errors at each set of β and m_0 . In the following, we focus on lattices with the renormalized anisotropy $\xi = a_s/a_t = 4$.

2. Lattice action

In the numerical simulations, we adopt Wilson gauge and staggered quark actions on anisotropic lattices. The Staggered quarks have several advantages over the Wilson-type quarks in studies related to the chiral symmetry and in simulations at lighter quark masses. The gauge action is

$$S_G = \beta \sum_x \left\{ \sum_{i < j}^3 \frac{1}{\gamma_G} \left[1 - \frac{1}{3} \text{Re Tr } U_{ij}(x) \right] + \sum_i^3 \gamma_G \left[1 - \frac{1}{3} \text{Re Tr } U_{i4}(x) \right] \right\}, \quad (1)$$

where γ_G is the bare gauge anisotropy parameter. The quark action is defined as

$$S_F = \sum_{x,y} \bar{\chi}(x) K(x,y) \chi(y). \quad (2)$$

$$K(x,y) = \delta_{x,y} - \gamma_F \kappa_\sigma \eta_4(x) \left[U_4(x) \delta_{x,y-\hat{4}} - U_4^\dagger(x-\hat{4}) \delta_{x,y+\hat{4}} \right] - \kappa_\sigma \sum_i \eta_\mu(x) \left[U_i(x) \delta_{x,y-\hat{i}} - U_i^\dagger(x-\hat{i}) \delta_{x,y+\hat{i}} \right] \quad (3)$$

where γ_F is a bare fermionic anisotropy parameter, $\eta_\mu(x)$ the staggered phase, $\kappa_\sigma = 1/2m_0$ with m_0 the bare quark mass in spatial lattice units.

Although these anisotropic lattice actions have been adopted in Ref.[8], they did not discuss the

systematic uncertainties due to the anisotropy to the sufficient level for precision computations.

3. Calibration procedures

The anisotropy parameters γ_G and γ_F should be tuned so that the physical isotropy condition, $\xi_G(\gamma_G^*, \gamma_F^*) = \xi_F(\gamma_G^*, \gamma_F^*) = \xi$ holds at each set of β and m_0 , where $\xi_G(\gamma_G, \gamma_F)$ and $\xi_F(\gamma_G, \gamma_F)$ are the renormalized anisotropies defined through the gauge and quark observables, respectively. In quenched simulations, one can firstly determine the γ_G independently of γ_F , and then tune γ_F for fixed γ_G . On the other hand, in dynamical simulations, γ_G and γ_F need to be tuned simultaneously.

3.1. Gauge sector

For the calibration in the gauge sector, we define $\xi_G(\gamma_G, \gamma_F)$ through the hadronic radii r_0 [9] in the spatial and temporal directions. Since we set the lattice scale via r_0 , the physical anisotropy is kept in the continuum extrapolation. This is an advantage to avoid that the systematic errors brought by the anisotropic lattice remain in the continuum limit.

The value of r_0 is defined with the static $q\bar{q}$ potential through the relation $r_0^2 F(r_0) = 1.65$, where $F(r)$ is the force between quarks. Then ξ_G is defined with the ratio of r_0 's in the temporal and spatial directions: $\xi_G = r_0^{(t)} / r_0^{(x)}$.

In quenched simulations, we can apply the Lüscher-Weisz noise reduction technique [10] and determine ξ_G at 0.2% level of accuracy [12]. In dynamical simulations, we instead apply the smearing technique to the anisotropic three-dimensional planes which enables determination of ξ_G at 1% level of accuracy.

3.2. Quark sector

In the fermion sector, we define ξ_F with the ratio of meson masses in temporal and spatial directions: $\xi_F = m_h^{(z)} / m_h^{(t)}$ [2]. We use the pseudoscalar channel, since in that channel the oscillating components of the correlators disappear quickly and hence statistical errors of masses are small.

Alternative definition of the ξ_F makes use of

Figure 1. The result of calibration of the staggered quark field in the quenched simulation.

the meson dispersion relation [11],

$$E^2(\mathbf{p}) = m^2 + \mathbf{p}^2 / \xi_F^2. \quad (4)$$

Here $E(\mathbf{p})$ and m are in temporal lattice units and $\mathbf{p}$ is in spatial lattice units, and hence ξ_F appears. $p_i = 2\pi n_i / L_i$ ($i = 1, 2, 3$), where L_i is lattice size in i -th direction. We use $\mathbf{n} = (0, 0, 0), (0, 0, 1)$ to define ξ_F .

At present stage of this work, we adopt the former procedure, with the ratio of the temporal and spatial meson masses, as the main calibration procedure for the quark field, because of smaller statistical uncertainties than the latter definition. In quenched simulation, we compare the results with these two procedures.

4. Numerical results of calibration

4.1. Quenched simulation

The simulation is performed on a $12^2 \times 24 \times 96$ lattice at $\beta = 5.75$ and $\gamma_G = 3.136$ which correspond to the spatial cutoff $a_\sigma^{-1} = 1.1$ GeV and the renormalized anisotropy $\xi_G = 4$ [12]. The statistics are 224 configurations. The bare quark mass range is from 0.01 to 0.5 which corresponds to the range m_{PS}/m_V from 0.33 to 0.90.

We calculate the meson mass ratio at several values of γ_F and interpolate them to γ_F^* at which $\xi_F = 4$ holds. The result is displayed in Fig. 1. For our lightest quark mass case, γ_F^* is deter-

mined within 0.5% statistical error.

In Fig. 1, we also show the result of calibration using the meson dispersion relation. The results of two procedures are consistent only in very light quark mass region. To understand the discrepancies of two procedures and large change of γ_F^* from the calibration with mass ratio at larger quark mass region are subjects of future work.

4.2. dynamical simulation

The simulation is performed with R-algorithm with $N_f = 2$ on lattices of the size $10^2 \times 20 \times 80$ at 4 values of β from 5.3 to 5.45 and the quark mass $m_0 = 0.1$. The statistics are from 300 to 800 trajectories after 200 for thermalization. In the

following we present only the result at $\beta = 5.3$ on which the spatial cutoff is $a_\sigma^{-1} = 0.69$ GeV and $m_{PS}/m_V = 0.6$.

We determine γ_G^* and γ_F^* by a linear interpolation to $\xi = 4$ using the 6 parameter sets of (γ_G, γ_F) assuming the following relations:

$$\begin{aligned}\xi_G &= a_0 + a_1(\gamma_G - \gamma_G^*) + a_2(\gamma_F - \gamma_F^*), \\ \xi_F &= b_0 + b_1(\gamma_G - \gamma_G^*) + b_2(\gamma_F - \gamma_F^*).\end{aligned}\quad (5)$$

The result of calibration with the meson mass ratio is presented in Fig.2.

The χ^2 fit results in $[a_0, a_1, a_2] = [4.000(24), 0.702(92), 0.075(92)]$, $[b_0, b_1, b_2] = [4.000(28), 0.220(08), 1.225(08)]$. We find that ξ_F has small dependence on γ_G and ξ_G on γ_F . By solving Eq. (5), we obtain $\gamma_G^* = 2.885(35)$, $\gamma_F^* = 2.955(31)$. We can tune the parameters γ_G and γ_F with the 1% level of statistical errors.

This calculation was done on a Hitachi SR8000 at KEK. H.M. and T.U. thank JSPS for Young Scientists for financial support.
